THEOREM OF THE DAY

The McIver–Neumann Half-*n* Bound *Let Ω be a set of order n, n ≠ 3, and let G be a permutation group acting on Ω. Then G may be generated by ⌊n/2⌋ elements.*

S= {(1 2)(3 4), (1 2 3 5)}

Sift(σ)
  while σ ≠1 and not done **do**
    i := smallest row no. moved by σ
    j := σ(i)
    if M_{ij} not empty **then** σ := σ × M_{ij}^{-1}
    else M_{ij} := σ and done := **true**

Schreier-Sims(S)
  Queue := S
  while Queue not empty
    σ := first permutation in Queue (thereupon removed)
    if Sift(σ) updates M with σ′ **then**
      add {M_{ij} × σ′, σ′ × M_{ij} | 1 ≤ i < j ≤ n, M_{ij} ≠ empty or $(\sigma')^{-1}$} to Queue

1	(1 2)(3 4)			
	1			
		1		
			1	
				1

1	(1 2)(3 4)		(2 4 3 5)	
	1			
		1		
			1	
				1

	1		(2 4 3 5)	
		1		
			1	
				1

(about 40 steps, with maximum Queue size about 30)

1	(1 2)(3 4)	(1 3 4 5)	(1 4 5 2)	(1 5)(2 4)
	1	(2 3)(4 5)	(2 4 3 5)	(2 5 3 4)
		1	–	–
			1	–
				1

The generation of a permutation group from a set of permutations is illuminated by the wonderful algorithm which Charles Sims derived from a 1927 lemma of Otto Schreier. In the illustration above, the algorithm is applied to a set of two permutations. The main work is done by the Sift routine, which first places (1 2)(3 4) into row 1 column 2 cell in the 5 × 5 table M. The next permutation $\sigma = (1\,2\,3\,5)$ is a candidate for the same cell since $\sigma(1) = 2$; since the cell is occupied by (1 2)(3 4) we calculate $\sigma := \sigma \times M_{12}^{-1} = (1\,2\,3\,5) \times (1\,2)(3\,4) = (2\,4\,3\,5)$. The new cell M_{24} is now indicated for σ because now $\sigma(2) = 4$. Subseqently, the queue is augmented in the main algorithm by pre- and post-multiplying (2 4 3 5) with each non-identity entry of M. The queue now begins with $(1\,2)(3\,4) \times (2\,4\,3\,5) = (1\,4\,5\,2)$ which Sift places directly into position $M_{1,4}$. Although the queue tends to grow rapidly it must eventually become empty; in the current example the algorithm terminates with table shown above, bottom-right. This table describes the generated group in the following way: the order of the group is the product of the numbers of permutations in each row, in this case $5 \times 4 \times 1 \times 1 \times 1 = 20$ (the group happens to be the Frobenius group of order 20, aka the Galois group of the polynomial $x^5 - 2$ over $\mathbb{Q}$); membership of the group is tested by running Sift on a candidate permutation σ which will be allocated to an empty table location if and only if it does not belong to the group. **Exercise:** try the algorithm with $\Omega = \{1, \ldots, 8\}$ and $S = \{(1\,2), (3\,4), (5\,6), (7\,8)\}$.

It is easy to generate large groups from a very few permutations; $n/2$ permutations may sometimes be necessary as the Exercise above easily shows. But Annabelle McIver and Peter M. Neumann's 1987 theorem seems to be deep and mysterious: it rests on the Classification of the Finite Simple Groups and suggests no obvious way of finding a generating set meeting its bound.
